Group Members: Ryan Jamison (asu6pt) Henry Jones (smu2sr), Austin Alvarado (hhk5mp), Wes Fletcher (zwa9fu)

Problem Space: The question we want to answer is how reliably can we predict the next pitch in a baseball game. In a game of persistent failure, giving hitters a slightly better chance at identifying the next pitch could win a team multiple extra games over the course of a season. We're currently deciding on the kind of model to build, but two frontrunners are a time series or a decision tree, and we most likely will build multiple and compare their results. The two baselines that this model must perform better than to be successful are always predicting the pitcher's most frequent pitch, and always predicting the most frequent pitch given circumstances (current count, lefty/righty most common).

Data: Since the four of us are working for the baseball team, we are still trying to figure out if we can use the UVA baseball team's in-house data. If we can't, we'll pull pitch data from statcast.com
